Appendix 5

Economic Update

At its 16 December meeting, the Monetary Policy Committee (MPC) voted 8-1 to raise Bank Rate by 0.15% from 0.10% to 0.25% and unanimously decided to make no changes to its programme of quantitative easing purchases due to finish in December 2021 at a total of £895bn.

The MPC disappointed financial markets by not raising Bank Rate at its November meeting. Until Omicron burst on the scene, most forecasters, therefore, viewed a Bank Rate increase as being near certain at this December meeting due to the way that inflationary pressures have been comprehensively building in both producer and consumer prices, and in wage rates. However, at the November meeting, the MPC decided it wanted to have assurance that the labour market would get over the end of the furlough scheme on 30th September without unemployment increasing sharply; their decision was, therefore, to wait until statistics were available to show how the economy had fared at this time.

On 10 December we learnt of the disappointing 0.1% rise in GDP in October which suggested that economic growth had already slowed to a crawl even before the Omicron variant was discovered in late November. Early evidence suggests growth in November might have been marginally better. Nonetheless, at such low rates of growth, the government's "Plan B" COVID-19 restrictions could cause the economy to contract in December.

On 14 December, the labour market statistics for the three months to October and the single month of October were released. The fallout after the furlough scheme ended on 30 September, (about one million people were still on furlough), was smaller and shorter than the Bank of England had feared: unemployment did not increase hugely in October. Indeed, vacancies rose to a record 1.219m in the three months to November showing there were acute shortages of labour.

These figures by themselves, would probably have been enough to give the MPC the assurance that it could press ahead to raise Bank Rate at this December meeting. However, the advent of Omicron in late November potentially threw a spanner into the works as it poses a major headwind to the economy which, of itself, will help to cool the economy. The financial markets, therefore, swung round to expecting no change in Bank Rate.

For the second month in a row, the MPC blind-sided financial markets, this time with a surprise increase in Bank Rate from 0.10% to 0.25%. What's more, the hawkish tone of comments indicated that the MPC is now concerned that inflationary pressures are indeed building and need concerted action by the MPC to counter. This indicates that there will be more increases to come with financial markets predicting 1% by the end of 2022. The 8-1 vote to raise the rate shows that there is firm agreement that inflation now poses a threat, especially after the CPI figure hit a 10-year high. The MPC commented that "there has been significant upside news" and that "there were some signs of greater persistence in domestic costs and price pressures".

On the other hand, it did also comment that "the Omicron variant is likely to weigh on near-term activity". But it stressed that at the November meeting it had said it would raise rates if the economy evolved as it expected and that now "these conditions had been met". It also appeared more worried about the possible boost to inflation form Omicron itself. It said that "the current position of the global and UK economies was materially different compared with prior to the onset of the pandemic, including elevated levels of consumer price inflation". It also noted the possibility that renewed social distancing would boost demand for goods again, (as demand for services would fall), meaning "global price pressures might persist for longer".

As for the timing of the next increase in Bank Rate, the MPC dropped the comment from November's statement that Bank Rate would be raised "in the coming months". That may suggest another rise is unlikely at the next meeting in February and that May is more likely. However, much could depend on how adversely, or not, the economy is affected by Omicron in the run up to the next meeting on 3 February. Once 0.50% is reached, the Bank would act to start shrinking its stock of QE, (gilts purchased by the Bank would not be replaced when they mature).

The MPC's forward guidance on its intended monetary policy on raising Bank Rate versus selling (quantitative easing) holdings of bonds is as follows: -

1. Placing the focus on raising Bank Rate as "the active instrument in most circumstances".
2. Raising Bank Rate to 0.50% before starting on reducing its holdings.
3. Once Bank Rate is at 0.50% it would stop reinvesting maturing gilts.
4. Once Bank Rate had risen to at least 1%, it would start selling its holdings.

COVID-19 vaccines have been the game changer which had enormously boosted confidence that life in the UK could largely return to normal during the second half of 2021 after a third wave of the virus threatened to overwhelm hospitals in the spring. The bursting onto the scene of the Omicron mutation at the end of November had threatened to cancel the Christmas holidays, but the Government decided not to impose more severe restrictions in the hope that this mild, but highly contagious variant, would not overwhelm hospitals. The big question is whether further mutations of the virus could develop which render current vaccines ineffective, as opposed to how quickly vaccines can be modified to deal with them and enhanced testing programmes be implemented to contain their spread.

In the US, during the first part of the year, US President Biden's, and the Democratic party's, determination to push through a $1.9trn (equivalent to 8.8% of GDP) fiscal boost for the US economy as a recovery package from the Covid pandemic was what unsettled financial markets. However, this was in addition to the $900bn support package already passed in December 2020. Financial markets were alarmed that all this stimulus was happening at a time when: -

1. A fast vaccination programme has enabled a rapid opening up of the economy.
2. The economy has been growing strongly during 2021.
3. It started from a position of little spare capacity due to less severe lockdown measures than in many other countries.
4. And the Fed was still providing stimulus through monthly QE purchases.

It was not much of a surprise that a combination of these factors would eventually cause an excess of demand in the economy which generated strong inflationary pressures. This has eventually been recognised by the Fed at its recent December meeting with an aggressive response to damp inflation down during 2022 and 2023.

At its 3 November meeting, the Fed decided to make a start on tapering its $120bn per month of QE purchases so that they ended next June. However, at its 15 December meeting it doubled the pace of tapering so that they will end all purchases in February. These purchases are currently acting as downward pressure on treasury yields and so it would be expected that Treasury yields will rise over the taper period, all other things being equal. It also forecast that it expected there would be three rate rises in 2022 of 0.25% from near zero currently, followed by three in 2023 and two in 2024, taking rates back above 2% to a neutral level for monetary policy.

In the Eurozone, the European Central Bank (ECB) joined with the Fed by also announcing on 16 December that it will be reducing its QE purchases - by half from October 2022, i.e., it will still be providing significant stimulus via QE purchases during the first half of 2022. Although headline inflation reached 4.9% in November, over half of that was due to energy but oil and gas prices are expected to fall sharply after the winter. As overall inflation will fall back sharply during 2022, it is likely that the ECB will leave its central rate below zero, currently -0.50%, over the next two years. The main struggle that the ECB has had in recent years is that inflation has been doggedly anaemic in sticking below its target rate of 2% despite all the ECB's major programmes of monetary easing by cutting rates into negative territory and providing QE support.

In China, the pace of economic growth has now fallen back after the initial surge of recovery from the pandemic and China has been struggling to contain the spread of the Delta variant through using sharp local lockdowns - which depress economic growth. However, with Omicron having now spread to China and being much more easily transmissible, this strategy of sharp local lockdowns to stop the virus may not prove so successful in future; this strategy poses a potential renewed threat to world supply chains. The People's Bank of China made a start in December 2021 on cutting its key interest rate to encourage flagging economic growth.

A summary overview of the future path of Bank Rate

- In December 2021, the Bank of England became the first major western central bank to put interest rates up in this upswing in the current business cycle in western economies as recovery progresses from the Covid recession of 2020.
- The next increase in Bank Rate could be in February or May, dependent on how severe an impact there is from Omicron.
- If there are lockdowns in January, this could pose a barrier for the MPC to putting Bank Rate up again as early as 3rd February.
- With inflation expected to peak between 5 and 6% in April, the MPC may want to be seen to be active in taking action to counter inflation on 5th May, the release date for its Quarterly Monetary Policy Report.
- However, rising gas and electricity prices last October and next April and increases in other prices caused by supply shortages and increases in taxation next April, are already going to deflate consumer spending power without the MPC having to take any action on Bank Rate to cool inflationary pressures.
- On the other hand, consumers are sitting on around £160bn of excess savings left over from the pandemic so when will they spend this sum, in part or in total?
- The December 2021 MPC meeting was more concerned with combating inflation over the medium term than supporting economic growth in the short term.
- Bank Rate increases beyond May are difficult to forecast as inflation is likely to drop sharply in the second half of 2022.

- However, the MPC will want to normalise Bank Rate over the next three years so that it has its main monetary policy tool ready to use in time for the next downturn; all rates under 2% are providing stimulus to economic growth.

- We have put year end 0.25% increases into Q1 of each financial year from 2023 to recognise this upward bias in Bank Rate - but the actual timing in each year is difficult to predict.

- Covid mutations remain a major potential downside threat in all three years as we are likely to get further mutations. How quickly can science come up with a mutation proof vaccine, or other treatment, – and for them to be widely administered around the world?
